

Cutting To Drown Invasive Phragmites

Special thanks to Greg Lisson and Leslie Wood (Oliphant Fishing Islands Phragmites Community Group) and Donna Stewart (South Bruce Peninsula Phragmites Group) for demonstrating the raspberry cane cutting method.

Tips for Cutting to Drown Phragmites

- » This method entails cutting the Phragmites stalk as close to the sediment as possible
- » The deeper the water, the greater the chance of starving the belowground structures of oxygen and drowning the plant
- » For sparse Phragmites, one of the handiest tools to use is a raspberry cane cutter sold by Lee Valley; made of lightweight aluminum it will not rust, can telescope from 30" to 46", and the blade can be sharpened or easily replaced
- » This tool allows for selective harvesting of invasive Phragmites when growing among native plants
- » Hold the plant with one hand and with the other place the hooked blade against the stalk below the lowest leaf, slide the blade down the stalk until it reaches the bottom, then give it a gentle tug toward you to sever the stalk
- » Be sure to remove all of the cut material from the water as it may re-sprout causing further spread; ice fishing sleds, canoes, kayaks, row boats, barges etc. are useful for collecting and transporting the cut material to dry land
- » Do not compost unless the area is contained and new shoots can be destroyed; if dried plants cannot be burned, burial to a depth of 1 m or storage in plastic bags until rotten are viable options
- » If seeds are present, pull plant over, place seed head inside a plastic bag and sever using pruners prior to cutting the stalk; dispose of seeds when rotten
